

# Math Diversion Problem 796

P. Reany

September 12, 2025

There's a time in your life before you understand  
generating functions, and a time after, and I  
can't think of anything that connects  
them than a leap of faith.

Title: Fibonacci Numbers Through Generating Functions

Presenter: Patrick

## 1 Problem

Introduce the Fibonacci numbers and then use generating functions to obtain the **Binet Formula**,

$$F_n = \frac{\varphi_+^n - \varphi_-^n}{\sqrt{5}}. \quad (1)$$

## 2 The Fibonacci Numbers

Leonardo Fibonacci was a thirteenth-century mathematician who helped to convince the Europeans to convert to the decimal number system we now enjoy in mathematics. But his fame comes from his publishing results on the so-called Fibonacci numbers, which had been known in antiquity to the mathematicians of India.

The Fibonacci sequence is based on the recursive definition: Starting with 0 and 1, add these two numbers to get 1.<sup>1</sup> Add the 1 and the 1 to get 2. Add the 1 and the 2 to get 3. Add the 2 and the 3 to get 5, and we have the start of an infinite sequence of numbers:  $\{0, 1, 1, 2, 3, 5, \dots\}$ . The sequence has the simple recursive formula

$$F_{n+2} = F_n + F_{n+1}, \quad (2)$$

---

<sup>1</sup>The literature on Fibonacci numbers shows the starting number as either 0 or 1, but the recurrence definition for these numbers is not affected.

where  $F_0 = 0$ ,  $F_1 = 1$ ,  $F_2 = 0 + 1 = 1$ ,  $F_3 = 1 + 1 = 2$ ,  $F_4 = 1 + 2 = 3$ , and so on. Given that this sequence is defined over the nonnegative integers, it has no ending and the numbers get big really fast:

$$\begin{aligned} &0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377, 610, \\ &987, 1597, 2584, 4181, 6765, 10946, 17711, \\ &28657, 46368, 75025, 121393, 196418, 317811, \dots \end{aligned} \quad (3)$$

Let's first investigate the progressive consecutive ratios of these numbers, say, starting with 377:

$$610/377 = 1.618037, \quad 987/610 = 1.618033, \quad 1597/987 = 1.618034, \dots \quad (4)$$

This new sequence of numbers looks like it may be approaching a famous number in mathematics, the **Golden Ratio**

$$\varphi = 1.61803398\dots \quad (\text{not rounded}). \quad (5)$$

Let's take a closer look at the Golden Ratio.<sup>2</sup>

According to the ancient Greeks, the Golden Ratio is said to occur as a relationship on the lengths of two adjacent sides of a rectangle<sup>3</sup> if, letting  $L$  stand for the length of the longer side and  $S$  the length of the shorter side, we get the proportion

$$\frac{L}{S} = \frac{L + S}{L}, \quad (6)$$

which is supposed to be a rectangle of maximal esthetic proportions (that is, of greatest beauty). Mind you, Equation (6) does not define the actual lengths of  $L$  and  $S$ , only their ratio.

Anyway, this equation has a numeric solution. Let  $x = L/S$  and substitute back into (6) to get

$$x = 1 + x^{-1}. \quad (7)$$

Multiplying this through by  $x$  and rearranging terms, we get the usual form of a quadratic equation:

$$x^2 - x - 1 = 0. \quad (8)$$

The quadratic formula gives us the two irrational roots

$$\varphi_{\pm} = \frac{1 \pm \sqrt{5}}{2}, \quad (9a)$$

or in decimal form:

$$\varphi_+ = 1.618033988\dots \quad \varphi_- = -0.618033988\dots \quad (9b)$$

In Euclidean geometry  $\varphi_-$  is "unphysical," but who knows? In a spacetime metric, the Golden Ratio may only need an alternative interpretation of  $\varphi_+$  as timelike and  $\varphi_-$  as spacelike, or something along those lines.

<sup>2</sup>According to Wikipedia, this relationship of the ratios of consecutive Fibonacci numbers to the Golden Ratio was first discovered by Johannes Kepler.

<sup>3</sup>We can talk about the Golden Ratio without mention of rectangles. Apparently the ancient Greeks divided line segments into the Golden Mean and used that idea to design features of the Parthenon, but this is a controversial claim.

### 3 Generating Function Approach

We naturally ask if we can come up with a nonrecursive form for the  $n$ th value of  $F_n$ .<sup>4</sup> One such form is the so-called Binet formula:

$$F_n = \frac{\varphi_+^n - \varphi_-^n}{\sqrt{5}}. \quad (10)$$

One way to discover a closed form is by the trick of employing a generating function.

A *generating function* is a formal power series whose coefficients are given by some sequence of numbers, particularly if there is a recurrence relation on the sequence. A generating function need not converge and we'll not take matters of convergence into account in this paper.

The idea of using a generating function is in two simple steps: First, can we take a combination of  $f(x)$  with powers of  $x$  such that all but a finite number of terms survive? If we can, then, by use of algebra, we can recast  $f(x)$  in a closed-form function of  $x$ .

Second, can we express  $f(x)$  as a formal power series? If we can, then we equate the two formal series and then equate coefficients of respective powers of  $x$ , and, hopefully, obtain a formula for the  $n$ th coefficient. It turns out that we can do this with the Fibonacci sequence.

Let  $f(x)$  be defined as follows

$$f(x) = \sum_{n=1}^{\infty} F_n x^n = F_1 x + F_2 x^2 + F_3 x^3 + \dots, \quad (11)$$

where the coefficients are the Fibonacci numbers defined as above. We have ignored the zero term  $F_0 = 0$ , as it will not contribute to the sum. Now, the way to get the typical term of such a sum to cancel is to employ the recurrence relation (2) in the form

$$F_{n+2} - F_{n+1} - F_n = 0. \quad (12)$$

To get the two minus signs, we multiply  $f(x)$  first by  $-x$  and then second by  $-x^2$ :

$$\begin{aligned} f(x) &= F_1 x + F_2 x^2 + F_3 x^3 + F_4 x^4 \dots \\ -x f(x) &= -F_1 x^2 - F_2 x^3 - F_3 x^4 - F_4 x^5 \dots \\ -x^2 f(x) &= -F_1 x^3 - F_2 x^4 - F_3 x^5 - F_4 x^6 \dots \end{aligned} \quad (13)$$

Now we just add them up and be amazed at all the cancellations:

$$(1 - x - x^2)f(x) = F_1 x + (F_2 - F_1)x^2 = x, \quad (14)$$

---

<sup>4</sup>This type of question is usual for mathematicians with or without a practical need to search for it. Yet, for practical considerations, wouldn't we rather have a closed form for the Fibonacci sequence to determine, say,  $F_{1000000}$  rather than to compute it from the recurrence relation (2)?

where the quadratic term drops out because  $F_1 = F_2$ , and the higher-order terms drop out because of Equation (12). Solving for  $f(x)$ , we get

$$f(x) = \frac{x}{(1-x-x^2)} = \frac{-x}{(x^2+x-1)}. \quad (15)$$

The following are a number of relations involving the  $\varphi_+$  and  $\varphi_-$  we will make use of soon:

---

$$\varphi_+ + \varphi_- = 1, \quad \varphi_+ - \varphi_- = \sqrt{5} \quad (16a)$$

$$\varphi_+^{-1} = -\varphi_-, \quad \varphi_-^{-1} = -\varphi_+ \quad (16b)$$

$$\varphi_+ \varphi_- = -1. \quad (16c)$$

---

The expression  $x^2 + x - 1$  factors as  $(x + \varphi_+)(x + \varphi_-)$ . From here we use partial fractions to get  $f(x)$  in the form of

$$\frac{-x}{x^2 + x - 1} = \frac{A}{(x + \varphi_+)} + \frac{B}{(x + \varphi_-)}. \quad (17)$$

My calculations give

$$A = -\frac{\varphi_+}{\sqrt{5}}, \quad B = \frac{\varphi_-}{\sqrt{5}}. \quad (18)$$

Then

$$\begin{aligned} f(x) &= \frac{1}{\sqrt{5}} \left[ \frac{-\varphi_+}{(x + \varphi_+)} + \frac{\varphi_-}{(x + \varphi_-)} \right] \\ &= \frac{1}{\sqrt{5}} \left[ \frac{-1}{(1 + y_+)} + \frac{1}{(1 + y_-)} \right], \end{aligned} \quad (19)$$

where  $y_+ = x/\varphi_+$  and  $y_- = x/\varphi_-$ . Now, expanding these two terms in power series, we get

$$f(x) = \frac{1}{\sqrt{5}} \left[ \sum_{n=0}^{\infty} -(-1)^n y_+^n(x) + \sum_{n=0}^{\infty} (-1)^n y_-^n(x) \right]. \quad (20)$$

Combining these summations and dropping out the zeroth terms, we get

$$f(x) = \frac{1}{\sqrt{5}} \sum_{n=1}^{\infty} (-1)^n [\varphi_-^{-n} - \varphi_+^{-n}] x^n. \quad (21)$$

Finally, using the results in (16b), we get

$$f(x) = \sum_{n=1}^{\infty} \left[ \frac{\varphi_+^n - \varphi_-^n}{\sqrt{5}} \right] x^n. \quad (22)$$

Making a term-by-term comparison of this last series with (11), we can conclude that

$$F_n = \frac{\varphi_+^n - \varphi_-^n}{\sqrt{5}}. \quad (23)$$

As a practical matter,  $\varphi_-^n$  goes to zero quickly as  $n$  goes large.
